
GROUP PROJECTS

Your task:

Enterprise Service Request Management System

- Design and implement a prototype of an internal enterprise system that allows employees to submit, track, and manage service requests.
- Many companies still handle internal requests through email, phone calls, spreadsheets, informal communication
- Consequently, requests get lost, responsibilities are unclear, status is not transparent, response times are inconsistent, and managers lack overview information
- Your task is to design and implement a better solution.

Enterprise Service Request Management System

- Your team will act as a small development team for a medium-sized company.
- You will:
 - analyze the business problem
 - define system requirements
 - create an object-oriented design
 - implement a working Java prototype
 - store data persistently
 - test and present your solution

Enterprise Service Request Management

- A medium-sized company wants one centralized system for internal service requests.
- Examples of requests:
 - IT support requests
 - facility issues
 - HR document requests
 - office supply requests
 - access or permission requests
- The company wants a system that standardizes request handling and improves transparency.

Main Roles

- Your system should support at least these roles:
- **Employee**
 - submits requests
 - views own requests
 - tracks status
- **Service Agent**
 - views open requests
 - processes requests
 - updates status
 - adds comments or resolution notes
- **Manager**
 - views requests across the system
 - monitors workload and status distribution
 - sees basic summary information

Mandatory Functions

- Your system must allow users to:
 - log in or simulate role-based access
 - create a request
 - assign a category and priority
 - update request status
 - view and search requests
 - store data persistently
 - validate input and handle errors appropriately

Request Lifecycle

- Each request should move through a defined lifecycle.
- Example statuses:
 - New
 - Assigned
 - In Progress
 - Waiting for Information
 - Resolved
 - Closed
- Your team must define sensible status transition rules.

Object-Oriented Analysis and Design

- Identify key domain classes
- You should think carefully about:
 - responsibilities
 - relationships between classes
 - good class design
 - encapsulation and modularity

Technology

- Your prototype should:
 - be implemented in Java
 - consist of multiple interacting classes
 - have a clear structure
 - use persistent data storage
 - include basic testing
 - be understandable and maintainable
- Keep the technical solution manageable. Focus on clarity and quality.

Deliverables

- Access: github repository (working release) + upload source code to canvas
 - documentation and instructions
 - An OOAD document (class diagram, explanation of key design choices)
 - Jira repository where you store your project management details that show how you progressed through your sprints (e.g., reviews and retrospectives)
- Provide
 - demonstration and interview in last session
 - statement of code provenance (in line with copyrights!, usage of tools)
 - statement of contribution
- Possible additional deliverables include:
 - a URL to a running web version of your project

Next Presentation

- Five to ten minutes total
- A concise introduction of the team (max 4-5 members)
- A brief pitch of the product vision (& maybe USPs?)
